Solving the clustering problem

We collected the data in a CSV file. We can inspect them using a text editor or a spreadsheet program. We can also import them into R

```
> wdir <- "D:/vlado/EDA/data"
> setwd(wdir)
> booksF <- paste("https://raw.githubusercontent.com/bavla/",</pre>
   "HSE/master/EDA/newBooks.csv", sep="")
> T <- read.csv2(url(booksF),stringsAsFactors=FALSE)</p>
> dim(T)
[1] 970
> nrow(T)
[11 970
> ncol(T)
[11 15
> head(T)
> tail(T)
> T[c(5,9,333),1:8]

```

The data obtained from our scraping program are "messy" – we need to *clean* them to be ready for analysis. This is true for most data obtained from different sources. After cleaning we *explore* the data to "get feeling" and ideas for analyses. Sometimes, if possible, we need to correct our scraping program and repeat the data collection. For larger data collections a test collection of a small sample is adwised. It is useful to preserve a copy of original raw data. Many problems can be resolved by correcting the original data in its copy. From the corrected data we construct a data frame (or some other structure) for analyses.

Clustering

Solving the clustering problem

Typical tasks in data cleaning

- correcting for unexpected values; consider extreme and influential units.
- normalization of values (dates in different formats; weights, money, lengths in different units; recategorization; unification: lower/upper case, nonASCII chars, '; names (first, last)).
- factorization of ordinal and categorical variables.
- splitting variables (date \rightarrow year, month, day; name \rightarrow first, last).
- combining variables (year, month, day → date).
- transforming variables (date → day of week; Box-Cox (1, 2, 3)).
- combining, adding data from other sources (geographical coordinates).
- · aggregating data.
- dealing with missing data.

Missing data

EDA, clean and explore

V. Batagelj

Cleaning

Explorin

Regression

Clustering

Solving the clustering

There are different options to deal with missing data:

- do nothing, mark with NA.
- find the value and insert it.
- remove the unit (in creating clean data frame).
- impute a value (guess, mean value, random, nearest neighbor, interpolation)

Identity (entity resolution) problem

EDA, clean and explore

V. Batagelj

Cleaning

Lxpioring

Regression

Clusterin

Solving the clustering

In dealing with data extracted from text sources we often encounter the *identity problem*. It has two parts:

- equivalence (different words/phrases representing the same term – synonyms); and
- ambiguity (same word/phrase representing different terms homonyms).

When dealing with names of people that include Chinese the "three Zhang, four Li" effect can make it to the surface.

The problem can be partially solved using dictionaries, considering context, using tools like stemming and lemmatization, etc.

For cleaning of Amazon data see the wiki page.

Solving the clustering problem

Exploration phase of data analysis gives us an initial insight in the data – we get feeling about variables and their relations. It also provides hypotheses for further analyses.

We usually start the exploration by looking at each variable separately (univariate). Besides numerical characteristics we use also visualizations according to the type of variable.

Later we look to relations among variables (multivariate). The two main types of relations are association (regression) and grouping (clustering).

Clusterin

Solving the clustering problem

Most of the standard distributions is available in R as functions. For a distribution *dist* are: dist - density g(x), $pdist - cumulative <math>F(x) = \int_{-\infty}^{x} g(t)dt$, $qdist - inverse - quantille function <math>q = F^{-1}(p)$, rdist - random numbers distributed according to*dist*.

Examples of *dist* (use help): unif, beta, binom, cauchy, exp, chisq, f, gamma, geom, hyper, lnorm, logis, nbinom, norm, pois, signrank, t, weibull, wilcox.

The function sample supports random sampling (replace=TRUE) from a given set.

Regression

Clustering

Solving the clustering problem

With an expression $y \sim f(x_1, x_2, \dots, x_k)$ we describe a *model* – relation between dependent variable and independent variables. There exist some functions that on the basis of data determine (parameters of) the function f optimizing some fit criterion: lm, gam, loess, lowess, ... The values of the model function in selected points are obtained using the function predict. The simplest model is the *regression* line:

```
> attach(mtcars)
> res <-lm(wt disp)
> res[[1]]
(Intercept]
1.599814597 0.007010325

Regression

Clusterin

Solving the clustering problem

From the selected class of functions \mathcal{F} we would like to select one that fits the best our data (x_k, y_k) , $k \in I$. Let's denote it with f(x, a). a are parameters. The error in a point (x_k, y_k) is equal to

$$y_k = f(x_k, a) + \varepsilon_k$$

These errors can be combined into a *total error* E(f) in different ways

$$E_1(f) = \sum_k |\varepsilon_k|$$
 $E_2(f) = \sum_k \varepsilon_k^2$
 $E_3(f) = \max_k |\varepsilon_k|$
 $E_4(f) = \text{lik}(f) = \prod_k f(x_k, a), \quad f \text{ is a distribution}$

First three min; E4 max.

Fitting

Cleanin

Explori

Regression

Clusterin

Solving the clustering

Instead with ε_k we can measure the point error also using some other quantities – *ortogonal* error ρ_k .

For fitting distributions the *maximum likelihood* (E_4) is usually used..

For general functions the *least squares method* (E_2) is used. In many cases it allows to get the solution analitically. Its main weakness is that it is very sensitive to outliers. Using computers also other, more robust methods became an option.

Weighted fitting

EDA, clean and explore

V. Batagelj

Cleanin

Regression

Clustering

Ciusterini

Solving the clustering problem

$$E(a) = \sum_{i} w_i \varepsilon_i^2 = \sum_{i=1}^n w_i (f(x_i, a) - y_i)^2$$

Measurements with precision $y_i \pm \sigma_i$; then $\varepsilon_i' = \frac{\varepsilon_i}{\sigma_i}$

$$E'(a) = \sum_{i} (\varepsilon'_{i})^{2} = \sum_{i} (\frac{\varepsilon_{i}}{\sigma_{i}})^{2} = \sum_{i} \frac{1}{\sigma_{i}^{2}} \varepsilon_{i}^{2}$$

Therefore $w_i = \frac{1}{\sigma_i^2}$.

Relative error: $y_i = f(x_i)(1 + \delta_i)$

$$\delta_i = \frac{y_i - f(x_i)}{f(x_i)} \approx \frac{y_i - f(x_i)}{y_i} \Rightarrow w_i = \frac{1}{y_i^2}$$

Is there a functional relation between given variables?

01....

Clusterin

Solving the clustering problem

Let $p(X) = (p(x_i))_{i=1}^n$ be a discrete pobability distribution. Its *entropy* is defined as

$$H(X) = -\sum_{i=1}^{n} p(x_i) \lg p(x_i)$$

where $\lg \equiv \log_2$ and $p = 0 \Rightarrow p \lg p = 0$.

It holds $0 \le H(X) \le \lg n$. For $p(x_k) = 1$; $p(x_i) = 0$, $i \ne k$ we have H = 0; and for $p(x_i) = \frac{1}{n}$, $i = 1, \dots, n$ we get $H = \lg n$. The *normalized entropy* $h(X) = \frac{H(X)}{\lg n}$ has values in [0, 1].

For discrete variables X and Y with distributions p(X) and p(Y) and joint probability distribution p(XY) their *information* is

$$I(X, Y) = \sum_{i=1}^{n} \sum_{j=1}^{m} p(x_i, y_j) \lg \frac{p(x_i, y_j)}{p(x_i)p(y_j)}$$

Considering $\sum_{i=1}^{m} p(x_i, y_j) = p(x_i)$ and $\sum_{i=1}^{n} p(x_i, y_j) = p(y_j)$ we get

$$I(X, Y) = H(X) + H(Y) - H(XY)$$

Raiski's coefficient

EDA, clean and explore

V. Batagelj

Cleanin

Explorir

Regression

01....

Giusterin

Solving the clustering problem

Information I(X, Y) has value 0 iff we have for all pairs $p(x_i, y_j) = p(x_i)p(y_j) - X$ and Y are independent.

The other extreme is attained iff X and Y are functionally related – in each row and each column of the distribution there is at most one nonempty cell, H(X) = H(Y) = H(XY) = I(X, Y).

In 1964 Raiski introduced a coefficient

$$R(X \leftrightarrow Y) = \frac{I(X, Y)}{H(XY)}$$
 or in directed version $R(X \to Y) = \frac{I(X, Y)}{H(Y)}$

Both take values in [0,1] and have value 0 when X and Y are independent

 $R(X \to Y) = 1$, when Y is a function of X; $R(X \leftrightarrow Y) = 1$, when the variables are linked one-to-one.

The Raiski's coefficient is defined for all types of scales.

Clustering

Solving the clustering problem

Given a set of units \mathcal{U} the clustering is a process of organizing units into groups – clusters of similar units. In real life clustering problems we have to deal with different theirs characteristics:

- description of units: vectors (types of measurement scales, number of variables, missing values, ...) or structured units;
- size of the set of units;
- structure of units "space" (density, shapes of clusters).

A recent book on clustering in R is the "Practical Guide to Cluster Analysis in R" by Alboukadel Kassambara (2017).

Lxploring

Regressio

Clustering

Solving the clustering problem

We approach the clustering problem as an optimization problem over the set of *feasible* clusterings Φ_k – partitions of units into k clusters. A cluster is a nonempty subset of the set of unit $\mathcal U$. The *criterion function* has the following form

$$P(\mathbf{C}) = \sum_{C \in \mathbf{C}} p(C)$$

The *total error* $P(\mathbf{C})$ of the clustering $\mathbf{C} = \{C_1, C_2, \dots, C_k\}$ is a sum of *cluster errors* p(C).

There are many possibilities how to express the cluster error p(C). Here we shall assume a model in which the error of a cluster is a sum of differences of its units from the cluster's representative T

$$p(C,T) = \sum_{X \in C} d(X,T)$$

Note that in general the representative needs not to be from the same "space" (set) as units.

Representatives, dissimilarities

EDA, clean and explore

V. Batagelj

Cleanin

Explorir

Regressio

Clusterina

Olusterini

Solving the clustering problem

The best representative is called a *leader*

$$T_C = \operatorname*{argmin}_T p(C, T)$$

Then we define

$$p(C) = p(C, T_C) = \min_{T} \sum_{X \in C} d(X, T)$$

In most cases we express the cluster error in terms of a *dissimilarity* between units d(X, Y); d(X, X) = 0 and d(X, Y) = d(Y, X).

Another example of cluster error is a diameter

$$p(C) = diam(C) = \max_{X,Y \in C} d(X,Y)$$

Clustering

Solving the clustering problem

Let $\mathbb{B} = \{0, 1\}$. For $X, Y \in \mathbb{B}^m$ we define a = XY, $b = X\overline{Y}$, $c = \overline{X}Y$, $d = \overline{X}\overline{Y}$. It holds a + b + c + d = m. The counters a, b, c, d are used to define several (dis)similarity measures on binary vectors.

In some cases the definition can yield an indefinite expression $\frac{0}{0}$. In such cases we can restrict the use of the measure, or define the values also for indefinite cases. For example, we extend the values of Jaccard coefficient such that $s_4(X,X)=1$. And for Kulczynski coefficient, we preserve the relation $T=\frac{1}{s_4}-1$ by

$$s_4 = \begin{cases} 1 & d = m \\ \frac{a}{a+b+c} & \text{otherwise} \end{cases} \qquad s_3^{-1} = T = \begin{cases} 0 & a = 0, \ d = m \\ \infty & a = 0, \ d < m \\ \frac{b+c}{a} & \text{otherwise} \end{cases}$$

We transform a similarity s from [1,0] into dissimilarity d on [0,1] by d=1-s.

For details see Batageli, Bren (1995).

Olusielli

Solving the clustering problem

Let \mathcal{F} be a finite family of subsets of the finite set U; $A, B \in \mathcal{F}$ and let $A \oplus B = (A \setminus B) \cup (B \setminus A)$ denotes the symmetric difference between A and B.

The 'standard' dissimilarity between sets is the *Hamming distance*:

$$d_H(A, B) := \operatorname{card}(A \oplus B)$$

Usually we normalize it $d_h(A,B) = \frac{1}{M} \operatorname{card}(A \oplus B)$. One normalization is $M = \operatorname{card}(U)$; the other $M = m_1 + m_2$, where m_1 and m_2 are the first and the second largest value in $\{\operatorname{card}(X) : X \in \mathcal{F}\}$.

Other dissimilarities

$$d_s(A, B) = \frac{\operatorname{card}(A \oplus B)}{\operatorname{card}(A) + \operatorname{card}(B)}$$
 $d_u(A, B) = \frac{\operatorname{card}(A \oplus B)}{\operatorname{card}(A \cup B)}$

$$d_m(A, B) = \frac{\max(\operatorname{card}(A \setminus B), \operatorname{card}(B \setminus A))}{\max(\operatorname{card}(A), \operatorname{card}(B))}$$

For all these dissimilarities d(A, B) = 0 if $A = B = \emptyset$.

Clusterina

Solving the clustering problem

the Gower dissimilarity coefficient for a mix of variables

$$d_{ij} = \sum_{v=1}^{m} \frac{\delta_{ijv} d_{ijv}}{\sum_{i=1}^{m} \delta_{ijv}}$$

where $\delta_{ij\nu}$ is a binary indicator equal to one whenever both observations i and j are nonmissing for variable ν , and zero otherwise. Observations with missing values are not included.

For binary and nominal variables v, $d_{ijv} = 0$ if $x_{iv} = x_{jv}$; and $d_{ijv} = 1$ otherwise.

Ordinal variables v are considered as categorical ordinal variables and the values are substituted with the corresponding position index, r_{iv} in the factor levels. These position indexes are transformed in the following manner $z_{iv} = \frac{r_{iv}-1}{\max_k r_{kv}-1}$ These new values, z_{iv} , are treated as observations of an interval scaled variable.

For continuous variables v,

$$d_{ijv} = rac{|x_{iv} - x_{jv}|}{\max_k(x_{kv}) - \min_k(x_{kv})}$$

 d_{ijv} is set to 0 if $\max_k(x_{kv}) = \min_k(x_{kv})$.

Finite - solution always exists, but in most cases algorithmically hard problem → heuristics.

- hierarchical
 - agglomerative methods (hclust, cluster/agnes, amap/hcluster, amap/hclusterpar)
 - divisive methods (cluster/diana, cluster/mona)
 - adding methods
- local optimization (leaders method) (kmeans, cluster/pam, cluster/clara, cluster/fanny)
- linear algebra methods
- graph theory methods
- other methods (mclust/Mclust, fpc/dbscan, dbscan/dbscan, factoextra/hkmeans)

Solving the clustering problem

Leaders method is a generalization of a popular nonhierarchical clustering k-means method.

The idea is to get "optimal" clustering into a pre-specified

number of clusters with the following iterative procedure:

determine an initial clustering

repeat

determine leaders of the clusters in the current clustering; assign each unit to the nearest new leader – producing a new clustering

until the leaders stabilize.

Hierarchical agglomerative clustering

Solving the clustering problem The *hierarchical agglomerative clustering* procedure is based on a step-by-step merging of the two closest clusters.

```
each unit forms a cluster: \mathbf{C}_n = \{\{X\} : X \in \mathcal{U}\}\ ; they are at level 0: h(\{X\}) = 0, \ X \in \mathcal{U}; for k = n - 1 to 1 do determine the closest pair of clusters (u, v) = \operatorname{argmin}_{i,j:\ i \neq j} \{D(C_i, C_j) : C_i, C_j \in \mathbf{C}_{k+1}\}\ ; join the closest pair of clusters C_{(uv)} = C_u \cup C_v \mathbf{C}_k = (\mathbf{C}_{k+1} \setminus \{C_u, C_v\}) \cup \{C_{(uv)}\}\ ; h(C_{(uv)}) = D(C_u, C_v) determine the dissimilarities D(C_{(uv)}, C_s), C_s \in \mathbf{C}_k endfor
```

 \mathbf{C}_k is a partition of the finite set of units \mathcal{U} into k clusters. The level h(C) of the cluster $C_{(uv)} = C_u \cup C_v$.

Clusterin

Solving the clustering problem Hierarchical methods differ in selection of a between cluster dissimilarity *D*:

- single linkage: $D(C_p, C_q) = \min_{X \in C_p, Y \in C_q} d(X, Y)$
- complete linkage: $D(C_p, C_q) = \max_{X \in C_p, Y \in C_q} d(X, Y)$
- Ward: $D(C_p, C_q) = \frac{n_p \cdot n_q}{n_p + n_q} d(T_p, T_q)$
- see help and paper
