Autocorrelation

Network
statistics

CUG

QAP

What else?

Resources

Assume that each node has score on continuous variable, such as age or rank.

Positive autocorrelation exists when nodes of similar value of variable tend to be adjacent

- Friendships tend to be homophilous wrt age
- Mentoring tends to be heterophilous wrt age

We can measure similarity via difference (Geary) or product (Moran).

Two measures were "borrowed" from spatial statistics:

- Geary's C

    - Also called Geary's [Contiguity] Ratio
    - Most sensitive to local autocorrelation

- Moran's I

    - Measures autocorrelation not only on variable values or location (adjacency), but rather on both simultaneously
    - More sensitive to global autocorrelatoin

- I is about covariation of pairs, C is about variation in variable values

Statnet `nacf`

Both measures are built in the statnet's `nacf`. It computes
dependence statistics for the given vector on network structure,
for neighborhoods of various orders. It produces a vector of
measures for multiple steps out into the network, up to the
theoretical maximum indicated by the order of the network.

For our purposes, we consider only the immediate neighborhood
around each node, meaning that we are interested in
autocorrelation between nodes that are just one step from one
another. The vector goes from 0 steps to however many nodes
are present in the network. Thus, the [2] in the scripts refers to
the second measure in the vector (one step).

Geary's C

netR, statistics

Autocorrelation

Network statistics

CUG

QAP

What else?

Resources

Let $a_{ij} > 0$ indicate adjacency of nodes u and v, and X_u indicate the score of node u on attribute X (e.g., age)

$$C = (n - 1)\frac{\sum_{u,v} a_{uv}(x_u - x_v)^2}{2\sum_{u,v} a_{uv} \cdot \sum_u (x_u - \bar{x})^2}$$

Range of values: $0 \leq C \leq 2$

- $C = 1$ indicates independence;

- $C > 1$ indicates negative autocorrelation;

- $C < 1$ indicates positive autocorrelation (homophily)

Moran's I

netR, statistics

V. Batagelj

Autocorrelation

Network
statistics

CUG

QAP

What else?

Resources

$$I = n \frac{\sum_{u,v} a_{uv}(x_u - \bar{x})(x_v - \bar{x})}{\sum_{u,v} a_{uv} \cdot \sum_u (x_u - \bar{x})^2}$$

Ranges between -1 and +1

- Expected value under independence is $\frac{-1}{n-1}$

- $I \to +1$ when positive autocorrelation

- $I \to -1$ when negative autocorrelation

Simple example

```
library(statnet)
g <- c(
  0, 1, 0,  1, 0, 0,  0, 0, 0,
  0, 0, 1,  0, 1, 0,  0, 0, 0,
  0, 0, 0,  0, 1, 0,  0, 0, 0,
  0, 0, 0,  0, 1, 0,  1, 0, 0,
  0, 0, 0,  0, 0, 1,  0, 1, 0,
  0, 0, 0,  0, 0, 0,  0, 0, 1,
  0, 0, 0,  0, 0, 0,  1, 0, 0,
  0, 0, 0,  0, 0, 0,  0, 0, 1,
  0, 0, 0,  0, 0, 0,  0, 0, 0  )
G <- symmetrize(matrix(g,byrow=TRUE,nrow=9))
rownames(G) <- colnames(G) <- c("A","B","C","D","E","F","G","H",
plot.sociomatrix(G)
gplot(G,gmode="graph",displaylabels=TRUE)
a1 <- c( 1, 2, 3, 2, 3, 4, 3, 4, 5 )
gplot(G,gmode="graph",displaylabels=TRUE,vertex.cex=a1)
nacf(G,a1,type="geary",mode="graph")[2]
nacf(G,a1,type="moran",mode="graph")[2]
a2 <- c(3, 4, 3, 4, 3, 2, 1, 2, 5 )
nacf(G,a2,type="geary",mode="graph")[2]
nacf(G,a2,type="moran",mode="graph")[2]
a3 <- c(4, 1, 4, 2, 5, 2, 3, 3, 3 )
nacf(G,a3,type="geary",mode="graph")[2]
nacf(G,a3,type="moran",mode="graph")[2]
```

Positive Autocorrelation

Similars adjacent; Geary's $C < 1$, Moran's $I > -0.125$
Node	Attrib
A	1
B	2
C	3
D	2
E	3
F	4
G	3
H	4
I	5

Geary's C: 0.333
Moran's I: 0.500

No Autocorrelation

Random pattern; Geary's $C \approx 1$, Moran's $I \approx -0.125$
Node	Attrib
A	3
B	4
C	3
D	4
E	3
F	2
G	1
H	2
I	5

Geary's C: 1.000
Moran's I: -0.250

Negative Autocorrelation

Dissimilars adjacent; Geary's $C > 1$, Moran's $I < -0.125$
Node	Attrib
A	4
B	1
C	4
D	2
E	5
F	2
G	3
H	3
I	3

Geary's C: 1.833
Moran's I: -0.875

Interpreting Autocorrelation

Moran's I ranges from -1 to 1 and is interpreted like Pearson's Correlation Coefficient.

- A value near +1.0 indicates clustering (adjacency tends to accompany similarity along a dimension)

- A value near -1.0 indicates dispersion (adjacency tends to accompany dissimilarity along a dimension)

- a value near 0 indicates random distribution (independence)

Geary's C ranges from 0 to 2. Just replace +1, -1 ond 0 in the above with 0, 2 and 1.

Florentine families

What is the dependance of the wealth of a family on marriage network?

```
> library(statnet)
> data(florentine)
> fw <- flomarriage %v% "wealth"
> gplot(flomarriage,displaylabels=TRUE,vertex.cex=0.025*fw,
+ gmode="graph",main='Florentine families')
> I <- nacf(flomarriage,fw,type="moran",mode="graph")
> I
          0          1          2          3          4
 1.00000000 -0.31073529  0.06531299 -0.06045322 -0.06267282  0.0
> C <- nacf(flomarriage,fw,type="geary",mode="graph")
> C
          0          1          2          3          4
0.000000000 1.683607336 0.811642725 0.899673648 0.826831324 0.00
> I[2]
          1
-0.3107353
> C[2]
          1
1.683607
```

We can see that the Florentine marriage network is (moderately, I=0.31) negatively (C = 1.68) autocorrelated with respect to the family wealth. Usually bride and spouse were not both equally rich.

Some issues with network statistics:

- Samples non-random

- Often work with populations

- Observations not independent

- Distributions unknown

One crucial thing in SNA is that even when networks are completely 'random' they exhibit certain non-random network features. For example, the embeddedment in triads. When a random network is dense, nodes will have a higher chance to be embedded in triads by default. Hence, you cannot really say that in one network nodes are more clustered than in another if you do not consider this.

General strategy

Network inference assuming conditional independence:

1. Calculate on the "observed" network a network statistic (global measure) that you are interested in.

2. Think about the properties of the network that you want to conserve.

3. Generate many "random" networks that have the same properties as the "observed" network.

4. Calculate the network statistic on these "conditional random networks" and compare this baseline distribution against the actually observed network statistic in the "observed" network.

Conditional Uniform Graphs (CUG)

This strategy is implemented in the sna function `cug.test` –
Conditional uniform graphs (CUGs).

It supports conditioning the simulated networks on three of the
possible modes (`cmode`): *size*; *number of edges*; and the
distribution of dyads. Select the conditioning mode according to
what you suspect about your own network of interest. (Note: CUG
can be made to condition on other properties.)

In the following example we will try for comparision all three
options. For a statistics we will use the betweenness
centralization. Centralization involves two items: the network
being analyzed; and the name of the centrality measure being
applied. Other global measures will, therefore, not require the
FUN.arg=list(), argument.

```
library(statnet)
data(florentine)
gplot(flobusiness,gmode="graph",displaylabels=TRUE)

rSize <- cug.test(flobusiness,centralization,
  FUN.arg=list(FUN=betweenness),mode="graph",cmode="size")
rEdges <- cug.test(flobusiness,centralization,
  FUN.arg=list(FUN=betweenness),mode="graph",cmode="edges")
rDyad <- cug.test(flobusiness,centralization,
  FUN.arg=list(FUN=betweenness),mode="graph",cmode="dyad.census"

# Aggregate results
Betweenness <- c(rSize$obs.stat,rEdges$obs.stat,rDyad$obs.stat)
PctGreater <- c(rSize$pgteobs,rEdges$pgteobs,rDyad$pgteobs)
PctLess <- c(rSize$plteobs,rEdges$plteobs,rDyad$plteobs)
report <- cbind(Betweenness, PctGreater, PctLess)
rownames(report) <- c("Size","Edges","Dyads")
report
```

	Betweenness	PctGreater	PctLess
Size	0.2057143	0.001	0.999
Edges	0.2057143	0.713	0.289
Dyads	0.2057143	0.738	0.263

Consider the visualization of the network. Given the network's structure, it is at least somewhat dominated by the Barbadori and Medici families (betweenness centralization = 0.21). But is that level of centralization special to the Florentine business network, or is this something that we would normally expect for a network this size? Is it something that we would normally expect for a network with this number of edges? Is it something that we would normally expect for a network with this distribution of dyads?

As we can see in the output above, this level of centralization is very uncommon in a network of this size. But it is not at all uncommon in a network with the same number of edges, or the same distribution of dyads.

We can depict the same information graphically by displaying the
distribution of betweeness centralization measures for the
randomly generated networks, and indicating where the
betweenness centralization measure of 0.21 lies in comparison to
each distribution.

```
par(mfrow=c(1,3))
plot(rSize,main="Betweenness \nConditioned on Size")
plot(rEdges,main="Betweenness \nConditioned on Edges")
plot(rDyad,main="Betweenness \nConditioned on Dyads")
par(mfrow=c(1,1))
```

QAP

What else?

Resources

Conditional Uniform Graphs (CUG)
Quadratic Assignment Procedure (QAP)

Quadratic assignment procedure (QAP) is similar to CUG, in that it uses simulation in order to generate a distribution of hypothetical networks. But QAP controls for network structure, as compared with CUG, which controls for size, the number of edges, or dyad census. QAP is useful for running a variety of statistics. It is based on the *permutation test*

- Get observed test statistic

- Construct a distribution of test statistics under null hypothesis

  - Thousands of permutations of actual data

- Count proportion of statistics on permuted data that are as large as the observed

  - This is the p-value of the test

Did the Florentine families base their business dealings on the marriage ties? (Or maybe their marriages are based on their business ties?)

Get the graph correlation value

```
> gcor(flobusiness,flomarriage)
[1] 0.3718679
```

Marriage and business ties are moderately correlated (r=0.37).
Is it significant?

```
> (rCor <- qaptest(list(flobusiness,flomarriage),gcor,
+    g1=1,g2=2,reps=1000))
QAP Test Results

Estimated p-values:
        p(f(perm) >= f(d)): 0.001
        p(f(perm) <= f(d)): 1
```

The correlation is significant at the 0.05 alpha level. We know this because less than 5% the permuted networks - or in this case, all of them - exhibited correlation coefficients that were either, greater than, or less than that of the value we calculated for these networks.

```
> plot(rCor, xlim=c(-0.25, 0.4))
```

Estimated Density of QAP Replications
